Nearly 300,000 children in the United States have some sort of arthritis. Arthritis can be short-term “lasting for just a few weeks or months, then going away forever” or it can be chronic and last for months or years. In about half of cases, it can last a lifetime. The most prevalent form of juvenile arthritis is juvenile idiopathic arthritis (JIA) (also known as juvenile rheumatoid arthritis, or JRA). ADHD: A Primer for Parents and Educators. BY ANNE M. HOWARD, PHD, Chicago School of Professional Psychology, IL STEVEN LANDAU, PHD, Illinois State University, Normal. Attention deficit hyperactivity disorder (ADHD) is a complex disorder characterized by three core symptoms of inattention, impulsivity, and hyperactivity. PROBLEMS ASSOCIATED WITH ADHD There is no doubt children with ADHD experience challenges in many aspects of daily living, at home, at school, and interacting with peers. Some of these problems may result from the ADHD-related symptoms, whereas other problems may be due to the same factors that cause ADHD. Regardless of the cause, each area of poor performance should be addressed with an appropriate intervention. At birth, children with PSE may be at risk for smaller head circumferences, lower birth weights, and may be small for gestational age [15,17]. During infancy they may have sleep difficulties as well as problems with state regulation (ie, inability to remain quiet, calm, and alert). Many foster parents select their local community physicians for initial and ongoing health care [22]. The PCP plays a central role in caring for foster children and therefore it is imperative for them to be familiar with current guidelines for health care evaluation recommended by the Child Welfare League of America (CWLA) and American Academy of Pediatrics (AAP) [23,24] as well as those of their own state and locality. There is an increased incidence of acute and chronic health problems for foster children [25,29].
